No potential conflict of interest was reported by the authors.

Funding:

This study benefited from a LABEX CORTEX (ANR-11-LABX-0042) funding of the University of Lyon, under the "Investissements d'Avenir" program (ANR-11-IDEX-0007) run by the French National Research Agency (ANR). It also benefited from a Région Auvergne-Rhône-Alpes grant (Direction des Finances 28/06) and from a Direction de la Recherche et des Ecoles Doctorales grant of the Université Lumière Lyon 2 (DRED n°13-2019). Finally, it was also financially supported by the Institute for Psychology of the Université Lumière Lyon 2.

1 **ABSTRACT**

2 **Introduction:** Interruptions are mostly related to negative outcomes and researchers already
3 found that the complexity or the length of interruptions modulate their deleterious effect on
4 performance. However, none of them investigated the effect of the pleasantness of
5 interruptions.

6 **Objective:** The objective of the study is to evaluate the impact of the pleasantness on both the
7 correct completion of the interrupting task and the time required to resume the primary task.

8 **Method:** We designed a realistic email searching primary task during which 46 participants
9 were either not interrupted or interrupted by a simple math addition task during which a
10 positive or a negative picture was progressively revealed. We then asked participants how
11 pleasant they found the interrupting task and investigated the effects of perceived pleasantness
12 both on the interrupting task and on resuming the primary task.

13 **Results:** Results showed that performance on the interrupting task was worst and the time to
14 resume the primary task was longer when participants found the task very pleasant or very
15 unpleasant. Performance in both tasks was the best when participants gave intermediate
16 pleasantness judgments. The findings were independent of the valence and arousal of the
17 pictures used to manipulate task pleasantness.

18 **Conclusion:** These results are discussed in light of empirical studies assessing the deleterious
19 effects of emotions on cognition, and practical implications are proposed.

Being able to complete a single activity from the beginning to its end without being interrupted is hard to achieve. Although literature provide some evidence of a beneficial effect of interruptions (Jett & George, 2003; O’Conaill & Frohlich, 1995; Zijlstra et al., 1999), in most of the cases, interruptions have detrimental effects on well-being and productivity (Couffe & Michael, 2017). Researchers focused on the factors that influence the resumption of the primary task after interruptions, for instance the complexity, the length, the frequency of interruptions or the time at which the interruption occurs (Borst et al., 2015; Brazzolotto & Michael, 2019; Monk et al., 2002; Zish et al., 2015). The pleasantness of a task may influence performance too, especially if it interrupts another one (Speier et al., 2003). **However, little is known about the effect of the pleasantness of interruptions.** Some researchers did nevertheless investigate the effect of emotional content of a task on individuals. For instance, Butts et al. (2015) showed that the affective tone of a message influences the emotional response of the recipient. Being interrupted can also trigger a positive or negative emotional response depending on the context (Sonnetag et al., 2018). However, little is known about the effect of the pleasantness of interruptions on both, the interrupting and the interrupted task performance. The current study thus focuses on the pleasantness of interruptions in order to highlight its foreseeable effect on an interrupted activity.

“A work interruption is an unexpected suspension of the behavioral performance of, and/or attentional focus from, an ongoing work task” (Puranik et al., 2020). The consequences of interruptions can take the form of a longer time to resume the primary task after the interruption (e.g. Blumberg et al., 2015; Brazzolotto & Michael, 2020; Monk et al., 2008), an increase in the time required to complete the primary task (e.g., Bailey & Konstan, 2006; Gupta, Li, & Sharda, 2013), a fall-off in accuracy (e.g., Drews & Musters, 2015) or an increase of stress (Bawden & Robinson, 2009). When the progression of the primary task is

52 interrupted, the operator has to switch to the interrupting task (Couffe & Michael, 2017). This
53 flexible behavior is possible by activating processes related to the new task and inhibiting
54 those related to the interrupted one. Resuming the interrupted task requires a new shift of the
55 operator's activity and the reactivation of the related processes shortly stored in memory
56 during the interrupting task. This forth and back behavior is resources consuming. Flexibility,
57 working memory, inhibition, and cognitive resources are thus involved in the resumption of
58 the primary task and are all should be influenced by the pleasantness of the task (Forgas,
59 2008).

60 The pleasantness of a task refers to “the pleasure or enjoyment it provides to
61 individuals” (Zenasni & Lubart, 2011; page 51). Pleasantness is very much linked to the
62 valence and the arousal of the content of the task (e.g. a positive content usually leading to a
63 subjective pleasure), but it does not represent how emotional the content is, but rather how
64 much the recipient loves it. Nevertheless, we could predict the effect of the pleasantness of a
65 task by the effect of the emotion on cognition. **On the one hand, completing a positive task**
66 **increases positive affect (Pictet et al., 2011), although there is no consensus on whether it**
67 **improves or impairs cognition and performance.** By impairing attention and generating
68 distracting thoughts, positive emotions decrease inhibitory control, disengagement from the
69 current task and flexibility, and impair information storage and retrieval from memory (Liu et
70 al., 2015; Martin & Kerns, 2011; Phillips et al., 2002; Rowe et al., 2007). However, there is
71 also evidence that positive emotion may enhance cognition. Indeed, by accelerating the
72 change of goals and rules, it seems to improve flexibility and creativity, but it also increases
73 working memory and facilitates orienting of attention (Pe et al., 2013; Pool et al., 2016; Wang
74 et al., 2017).

75 Negative emotions, on the other hand, increase cognitive demands, decrease working
76 memory and disengagement from the current task, and interfere with cognitive control and

77 inhibition (Georgiou et al., 2005; Kensinger & Corkin, 2003; Song et al., 2017). However,
78 negative emotions also create an initial mobilization process that directs attention and
79 behavior toward solving the problem, in order to mitigate and repair the impact of the
80 negative event (Taylor, 1991). This can be beneficial to the extent that the narrowing of
81 attentional focus helps the individual focus on an ongoing task and complete it more
82 accurately. A more recent study also showed that negative emotions increase mnemonic
83 precision (Xie & Zhang, 2017). The inconsistency in the above-mentioned findings may be
84 due to the methodological difference between the studies, such as the way emotion was
85 assessed and the experimental paradigm.

86 Since processing an interruption involves flexibility, working memory, inhibition and
87 cognitive resources (Couffe & Michael, 2017) and emotions seem to affect all these
88 processes, we may hypothesize that emotion can exert an influenced performance in the
89 context of interruptions, without knowing if the influence provides positive or negative
90 outcomes. To test this hypothesis, a realistic primary task of email search interrupted by
91 another task consisting of simple math additions, the completion of which revealed
92 progressively a ground picture of negative or positive valence, was proposed. The objective of
93 the study is to evaluate the impact of these pictures on both the correct completion of the
94 interrupting task (i.e., math additions) and the required to resume the primary task.

95 **2. MATERIAL AND METHOD**

96 2.1. Participants

97 Forty-six volunteers (18 male, 28 females; mean age = 20.4 ± 1.8 years) took part in
98 this experiment. Participants were recruited among undergraduate students in classrooms
99 from varied fields of study. All had normal or corrected-to-normal vision and reported no
100 specific characteristics that could influence their performance. The experiment was
101 administered in a closed room in the laboratory and each participant completed it alone. An

102 informed consent was obtained from each participant. This research complied with the
103 American Psychological Association Code of Ethics and the tenets of the Declaration of
104 Helsinki.

105 2.2. Stimuli and material for the Primary Task

106 The primary task was an email searching task similar to the one used by Brazzotto
107 and Michael (2019). Each page (see Figure 1) contained a list of emails at the center of the
108 screen, a bar with the search criteria and a trash icon at the top, a banner with options on the
109 left, and ads on the right. The option bar and the ads did never change during the experiment
110 and the participants could not interact with them. Each list consisted of 30 emails, each of
111 which was displayed on a separate line. Each line contained relevant elements to the task: an
112 empty square, the name of the sender, a colored circle (either blue, light-gray or black), and
113 an attachment symbol (a paper clip). Irrelevant elements were added in order to create a
114 realistic inbox environment and were used as distractors for the visual selective attention task:
115 a star (either black or white), a blue flag (either present or not), the subject line, the first
116 words of the email, and the date of sending.

117 The participants were instructed to click on the boxes displayed on the left of each
118 target email (causing a check mark to appear inside them). Target emails were described by a
119 combination of three criteria listed above the emails list. These were the name of the sender
120 with an adjacent circle in a specific color and a paper clip indicating the presence of an
121 attachment (e.g. Pierre Michon – blue circle – paper clip). Each page contained 10 target
122 emails. In each new trial and for each email item, the search criteria and the sender names
123 were different. When participants had finished scanning the page, they had to make a new
124 page appear by clicking on the trash icon.

125

127

128 2.3. Stimuli and material for the Interrupting Task

129 For the purpose of the study, thirty pictures (15 positive and 15 negative) were
130 preselected from the International Affective Pictures System (IAPS; Lang, Bradley, &
131 Cuthbert, 1999). We then asked a different sample of 66 participants (30 male, 36 females;
132 mean age = 20.2 ± 1.4 years), to judge the valence and the arousal of each picture with a 9-
133 point SAM Scale (Bradley & Lang, 1994). Among those pictures, 20 (10 positive and 10
134 negative) were selected with the caution that the mean arousal level for positive and negative
135 pictures be similar (see Table 1). Each picture was used as a visual background during the
136 interrupting task.

137 The interrupting task was an addition task. Participants saw successively 8 simple
138 math additions (24-point Calibri white font) ranging from “0 + 0” to “9 + 9”.

139

140 Please insert Table 1 here

141

142 2.4. Procedure

143 Each trial consisted of one inbox page and the participants completed 30 trials. Twenty
144 trials were postponed by the interrupting task, which contained either a positive picture (10
145 trials) or a negative picture (10 trials). Remaining trials were uninterrupted. The tested
146 conditions were randomly presented.

147 Participants were not informed of the presence of interruptions, but they were
148 instructed to complete the task displayed by the program, as quickly and accurately as
149 possible. When the trial should contain an interruption, the interrupting task appeared after
150 that a certain number of target emails between 1 to 9 (randomly and equiprobably chosen by
151 the computer) was selected. A black screen thus covered the inbox page and the interrupting
152 task started. Simple math additions were then presented on the screen one by one. Each

153 addition appeared for 3 seconds and the participants had to type his answer on the keyboard.
154 Whatever the answer given by the participant (right, wrong or no answer), 1/8th of a ground
155 picture was revealed (see Figure 2). Responding quickly did not make the image appear
156 faster. A new addition was then presented, and so on until the 8 additions were completed.
157 The full picture was visible at the end of the eighth addition and remained on the screen for 2
158 seconds. Then, the inbox page reappeared, and all selected emails before the interruption
159 remained selected. The participants continued to search for target emails and finish the trial
160 by clicking on the trash icon. If the trial contained an interruption, participants then saw the
161 picture displayed during the task and they had to judge it in three ways with a modified 9-
162 point SAM Scale (Bradley & Lang, 1994). First, participants judged the degree at which the
163 picture made the interrupting task pleasant (1 = very unpleasant; 9 = very pleasant). Then,
164 participants judged the valence of the picture (1 = very negative; 9 = very positive). Finally,
165 participants judged the arousal of the picture (1 = not arousing at all; 9 = very arousing). After
166 that, a new inbox page appeared.

167

168 Please insert Figure 2 here

169

170 We collected two dependent variables : (i) the accuracy, i.e. the percentage of correct
171 responses obtained in the interrupting tasks and (ii) the Resumption Lag (RL), i.e. the time
172 that elapsed between the end of the interrupting task and the first next selected email in the
173 primary task (Altmann and Trafton, 2002). We also extracted the mean time to select an email
174 in uninterrupted trials, that we called Inter-Click-Interval (i.e. ICI), to be a control variable for
175 RL.

176 **3. RESULTS**

177 Analyses were carried out with Statistica 12.0. We conducted correlations, trial-by-
178 trial Analyses of Variance (ANOVA) with Bonferroni-corrected comparisons and mediation
179 analyses. When the participants did not select enough target emails in order to trigger the
180 interruption, the trial were removed from analyses. Thus, 10% of interrupted trials were
181 removed. The aim was to use task pleasantness as dependent variable. However, because
182 some participants did not rate the interrupting task using the entire scale (1 to 9), the resulting
183 table of means was incomplete (e.g. a participant never rated the pleasantness of the
184 interrupting task as 3 and 6), and 33 % of the values were missing. Therefore, trial-by-trial
185 analyses were used since using subjects as a grouping factor in a repeated measures analysis
186 was impossible. Autocorrelations were computed in order to ensure that trials were
187 independent from each other. The lag 1 autocorrelation coefficient was obtained for each
188 participant and, subsequently, the average autocorrelation coefficient of the whole sample was
189 computed using the Fisher transform. For accuracy, the autocorrelation coefficient was not
190 significant ($r = -0,063$; $p = 0.68$), neither for Resumption Lag ($r = 0.018$; $p = 0.90$). This
191 suggests that the trials can be considered as being independent from each other and trial-by-
192 trial analyses can be used.

193 First of all, we conducted trial-by-trial correlations analyses on valence, arousal, and
194 task pleasantness. A positive correlation was found between valence and task pleasantness
195 ($r = 0.81$, $p < .01$) and a negative correlation between valence and arousal ($r = -0.15$, $p < .01$)
196 and between arousal and task pleasantness ($r = -0.15$, $p < .01$).

197 The second step consisted in assessing the influence of task pleasantness on accuracy
198 in the interrupting task independently of the valence and the arousal of the ground pictures,
199 and the timing of the interruption. To this aim, we first extracted the residual accuracy on the
200 basis of multiple regression analyses with trial-by-trial accuracy as dependent variable, and
201 valence, arousal of pictures and timing as predictors. The residual accuracy was then used in a

202 trial-by-trial ANOVA with the score of task pleasantness (from 1 to 9) as inter-trial factor.
203 The main effect of task pleasantness was significant (see Figure 3; $F_2(8, 823) = 3.56, p < .01,$
204 $\eta^2p = 0.03$). A V-shaped curve was observed with accuracy being the lowest when the
205 interrupting task was judged only as being extremely pleasant (i.e., 9) or very unpleasant (i.e.,
206 2). Accuracy was the highest for median scores of pleasantness (5). Bonferroni-corrected
207 comparisons showed that the only reliable differences were found between 2 and 5 ($p < .04$)
208 and between 5 and 9 ($p < .02$); no difference was found between 2 and 9 ($p = 1.0$).

209 Since, the V-shaped curve resembles the Yerkes-Dodson law (Yerkes & Dodson,
210 1908), which states that performance is an inverted V-shaped as a function of arousal, we
211 decided to conduct a trial-by-trial ANOVA on the residual accuracy (computed with the
212 valence of pictures, the perceived task pleasantness and timing as predictors) with the score of
213 pictures arousal (from 1 to 9) as inter-trial factor. The main effect of pictures arousal was not
214 significant ($F_2(8, 823) = 1.79, NS, \eta^2p = 0.02$). In the same way, the main effect of valence
215 of the pictures was not significant ($F_2(8, 823) = 0.39, NS, \eta^2p = 0.004$).

216

217 Please insert Figure 3 here

218

219 The third step was to demonstrate that the occurrence of an interruption, whatever its
220 pleasantness, affected the performance of the interrupted primary task. A trial-by-trial
221 ANOVA was used to compare ICI and RL. The analysis showed that RL (5.26 s) was
222 significantly longer than ICI (3.36 s; $F_2(458) = 403.06; p < .001; \eta^2p = .47$), suggesting a
223 deleterious effect of interruptions on the email search.

224 Finally, the effect of the pleasantness of the interrupted task on the primary task was
225 assessed through the analysis of RL. The same logic was as before. We first extracted the
226 residual RL on the basis of multiple regression analyses with trial-by-trial RL as dependent

227 variable, and valence and arousal of pictures and timing as predictors. The residual RL was
228 then used in a trial-by-trial ANOVA with the score of task pleasantness of the interrupting
229 task (from 1 to 9) as inter-trial factor. The main effect of task pleasantness was significant
230 (see Figure 3; $F_2(8, 823) = 3.44, p < .01, \eta^2p = 0.03$). Once again, a V-shaped curve was
231 observed with RL being the slowest in the extremities (1 and 9) and the shortest for the
232 median score (5). Bonferroni-corrected comparisons showed that the only reliable differences
233 were found between 1 and 5 ($p < .01$) and between 5 and 9 ($p < .04$); no difference was found
234 between 1 and 9 ($p = 1.0$).

235 Just as for accuracy, we decided to conduct a trial-by-trial ANOVA on the residual RL
236 (computed with the valence of pictures, the perceived task pleasantness, and timing as
237 predictors) with the score of pictures arousal (from 1 to 9) as inter-trial factor. The main effect
238 of arousal of the pictures was not significant ($F_2(8, 823) = 0.58, NS, \eta^2p = 0.006$). In the
239 same way, the main effect of valence of the pictures was not significant
240 ($F_2(8, 823) = 1.34, NS, \eta^2p = 0.01$).

241 The same pattern of results was thus found for the effect of task pleasantness on
242 accuracy and RL. However, a question remains: does task pleasantness influences directly the
243 RL or does it affect accuracy at first place which in turns influences RL? Indeed, succeeding
244 the task may be a factor of pleasantness. Therefore, a mediation analysis was conducted with
245 task pleasantness as the independent variable, the RL as the dependent variable and accuracy
246 as the mediator. The analysis did not reveal a mediated effect of accuracy (Sobel $z = -1.5,$
247 $p = .13$; Sobel, 1982).

248 **4. DISCUSSION**

249 The current study was conducted in order to investigate the effect of the pleasantness
250 of an interrupting task on completing it, as well as on the time taken to resume a primary task.

251 Participants were required to find target emails among distractors and could be interrupted by
252 a task the background picture of which could render it pleasant or unpleasant.

253 As shown many times before, we found that interrupting the primary task slowed
254 down performance (Blumberg et al., 2015; Hodgetts & Jones, 2006). However, our results
255 mainly showed that the more the participants found the interrupting task pleasant or
256 unpleasant, the worst they performed in it. Furthermore, under the same conditions,
257 participants took more time to resume the primary task. Interrupting tasks that were judged as
258 being rather neutral (or of intermediate pleasantness) were the less deleterious both for the
259 interrupting task and the interrupted one.

260 That very pleasant and very unpleasant interrupting tasks are less well performed
261 could be due to the fact that performing emotion-charged tasks is resources consuming,
262 whether pleasant or unpleasant (Yiend, 2010). Cognitive resources being limited, few remain
263 available to complete the task, thus performance decreases.

264 That the time to resume the primary task was the longest with very pleasant and very
265 unpleasant interrupting tasks could be understood by the impairment by emotions of processes
266 underlying the resumption of the primary task: flexibility, working memory, inhibition, and
267 cognitive resources. Switching from an emotion-charged interrupting task seems to be more
268 difficult because flexibility has been shown to be impaired by positive emotions through
269 distracting thoughts and slowing attentional shifting (Phillips et al., 2002). But also, negative
270 emotions may dampen flexibility through impairing disengagement (Georgiou et al., 2005).
271 Positive and negative emotions have also been shown to impair working memory (Kensinger
272 & Corkin, 2003; Martin & Kerns, 2011), leading to disrupt the storage of processes related to
273 the primary task, thus increasing the time to reactivate them once the interruption is over. By
274 capturing attention, emotions could interfere with current processes and decrease performance
275 (Liu et al., 2015; Song et al., 2017). Therefore, it could be more difficult to inhibit an

276 interrupting task and move on when it is emotion-charged. Finally, the allocation of cognitive
277 resources is seemingly hindered by emotions, which demand a great amount of cognitive
278 resources (Yiend, 2010). Being limited (Kahneman, 1973), dividing resources during the
279 interruption should then be more difficult, resulting in a higher deactivation of processes
280 related to the primary task and then a longer time to resume it. However, this remains heavy
281 speculative since there are no clear clues as far as which of these processes is the most
282 impacted, and this constitutes a limitation of the present study. Future investigations could
283 shed some light on this issue.

284 Alternative explanations are nevertheless plausible. The weakest performance at the
285 interrupting task and at the resumption of the primary task may come from an attentional
286 residue resulting from the switch of task. Indeed, task switching leads to cognitively linger on
287 the suspended task, which has been shown to affect performance on the interrupting task.
288 (Leroy, 2009). When being interrupted by the addition task, the participants may be still
289 cognitively thinking of the email task, which may have resulted in low accuracy. However,
290 this theory cannot explain why performance is different depending on the pleasantness, as
291 there is nothing to suggest that doing a task that is pleasant or unpleasant will lead to higher
292 attentional residue from the primary task. Achieving a goal by progressing through the
293 interrupting task could also explain a drop in performance, since it has already been shown
294 that goal progress on the interrupting task has been linked to positive affect, affecting
295 outcomes (Sonnentag et al., 2018). Once again, there is no indication in this theory that the
296 goal is influenced by the pleasantness of the interrupting task.

297 Overall, our results support that task pleasantness has a deleterious effect on cognition
298 and performance, and this tallies well with numerous studies which found similar effects of
299 emotions with simpler and less naturalistic tasks. Moreover, we found a pattern similar of the
300 Yerkes-Dodson law (Yerkes & Dodson, 1908), but the analysis showed that the V-shaped

301 curve of performance was due to task pleasantness, not to arousal. Our study is novel in
302 several regards. Usually, the effect of emotions is investigated after manipulating the valence
303 or the arousal and the effects are analyzed as a function of these manipulations. Here, instead,
304 we used the judgment of pleasantness provided by each participant for each ground picture
305 and in each new trial as independent variable in order to assess its effect on trial-by-trial
306 performance. Moreover, all effects were analyzed independently of the perceived valence and
307 arousal of every single items. This ensured that what was assessed was truly and solely the
308 pleasantness of the interrupting task as perceived by each participant. Finally, we are also, to
309 our knowledge, the first to assess the effect of the pleasantness of the interrupting task on task
310 completion, showing that it may affect not only the interrupting task but also the interrupted
311 one. We thus showed some effects on the current performance, and some after-effects when
312 trying to move one. Our results could probably be extended to a real-world situation mainly
313 because of the naturalistic and ecological aspect of our paradigm. For instance, we
314 investigated the pleasantness through the use of ground pictures, but this could also be
315 achieved through doing repetitive and annoying activities or creative and stimulating ones, or
316 even through the work atmosphere and pressure. Would the results be similar? Many
317 questions merit answers for better understanding how the pleasantness of interruptions could
318 influence productivity and well-being at work and then resolve the subsequent issues. This
319 study nevertheless has some practical implications. We have shown that the emotional content
320 of a task negatively affects individuals' performance, as much on the task itself as on the
321 resumption of the primary task. It therefore questions the way notifications, or the content of
322 emails are designed. It can indeed be assumed that pop-ups designed with colors or images to
323 attract users are to be avoided in favor of more neutral backgrounds. It can also be
324 extrapolated that, as firstly studied by Butts et al. (2015), the emotional content of the
325 message received by email or instant messaging will influence performance. We thus can

326 hypothesize that a message that is neither too cold nor too warm, what should not please or
327 displease the recipient, will have a less deleterious effect on him or her. However, these
328 recommendations are the complete opposite of current practices, which aim to attract as much
329 attention from users as possible, without thinking about the harmful consequences for them.

330 The study has some limitations yet. The magnitude of the effects was low, suggesting
331 that the effect of pleasantness was small, even if it exists. The number of trials was also quite
332 large, what could have led to an overestimation of the significance of our trial-by-trial
333 analyses (comparing to participant-to-participant analyses). Moreover, the collection of
334 judgements was problematic since we wanted to ask the participant during or right after the
335 interrupted task, but this would break the continuity of the task. Collecting the judgements
336 between two trials was thus decided, but we are aware that times are spent before the
337 collection. Finally, the choice of the interrupting task can be discussed. Presenting the pictures
338 as puzzles differed from the literature, but we wanted participants to stay motivated in order
339 to ensure that induction works. We also used pictures of the IAPS because, although they are
340 quite old, they are frequently used.

341 In conclusion, very pleasant interrupting tasks as much as very unpleasant ones were
342 both performed less well and, as a negative after-effect, impaired performance on the task that
343 was interrupted. Our results provide empirical support to the deleterious effect of emotions on
344 cognition, especially in the context of an interrupted activity.

345

346 Both authors declare that they have no conflict of interest.
